(c) Discuss the anatomical changes that occurred in Man due to erect postureDo not
write
anything in
this margin

Erect Posture was one of the most significant steps in the process of hominidization:

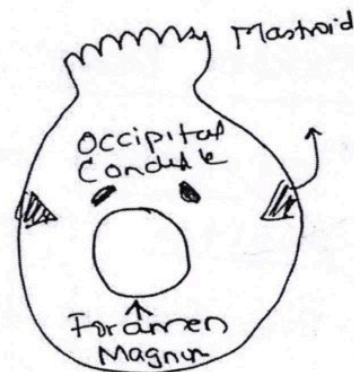

① Head & Skull

→ Foramen Magnum moved downward and forward so spinal cord enters skull at bottom.

→ Occipital Condyles were moved toward the jaws.

→ Development of Mastoid process that helped balance head on spine.

Fig 1

Inferior view of Skull

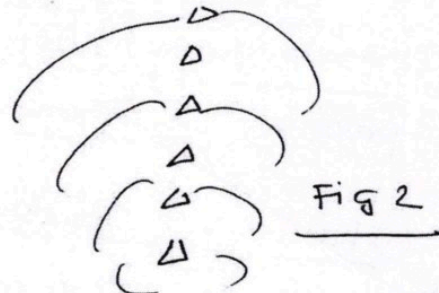

② Middle Body

→ 4 curves in the spine which are dorsal, lumbar, sacral & cervical.

→ Size of the

Double S
Shaped
Spine

vertebrate became larger.
→ Relative constancy in spines L2A™
combining from
the ribs helped
evenly distribute
the weight.

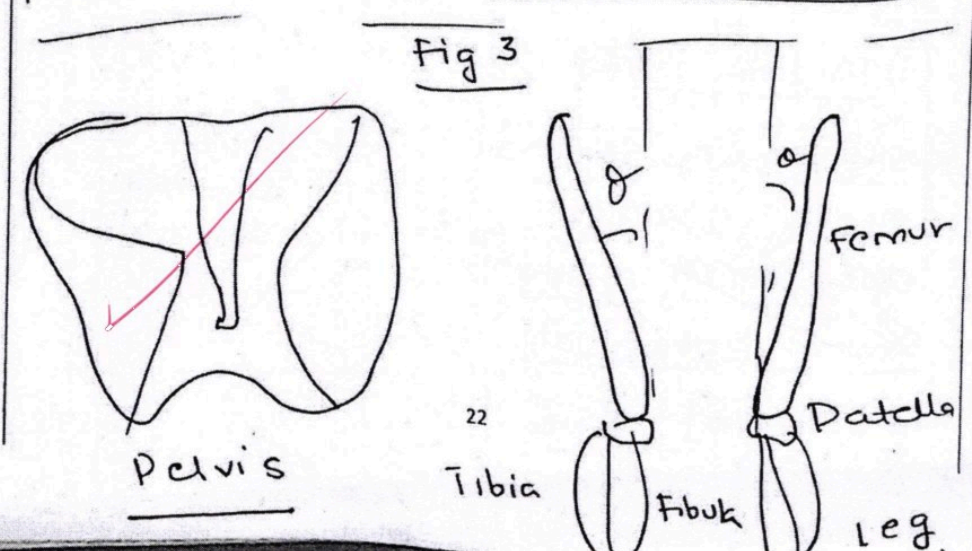

→ The Sacrum & Thoracic cage
coccyx bones are
fused for strength.

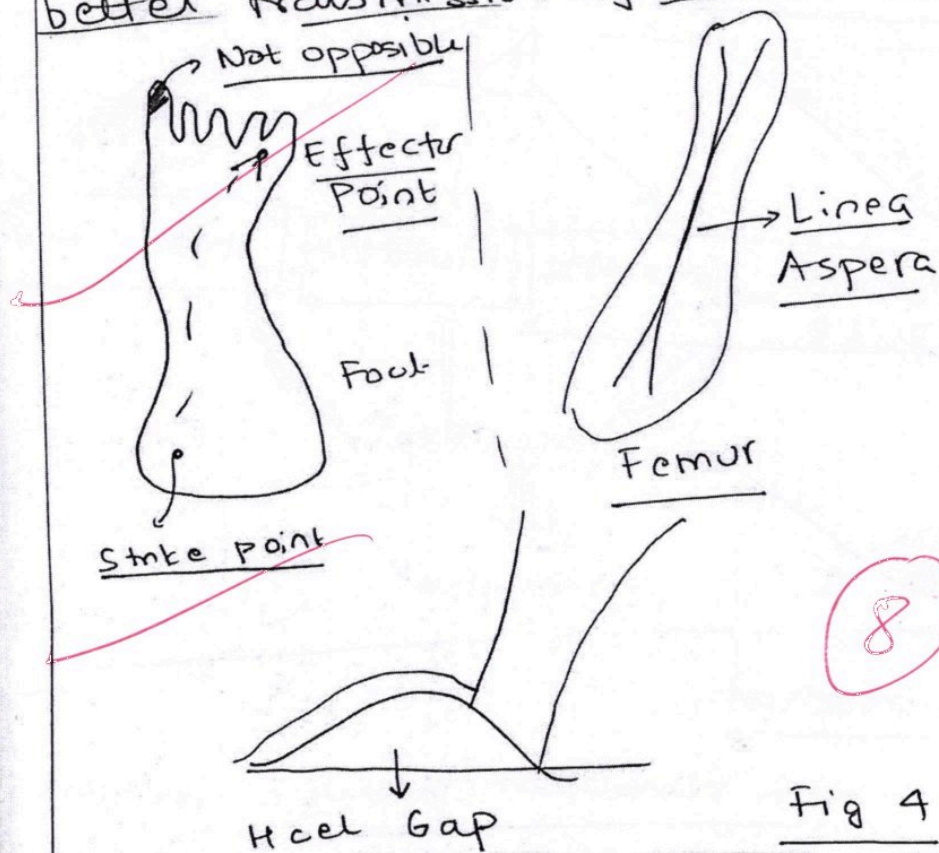

③ Lower Body

→ The pelvis is basin shaped &
shorter than apes.

→ The femur is strongest bone in
the body & has ridge on
posterior side ⇒ Linea Aspera.

- The femur is angled in **L2ATM** towards the patella so that the body lies above the knees.
- The sacrum-pelvic joint is closer to the pelvic-femur joint for better transmission of weight.

Thus all these analytical changes helped man roam the Savannahs and conquer new areas. So biocultural evolution of man occurred.
