(c) Humans are still subjects of natural selection in many ways in today's world. Discuss 15

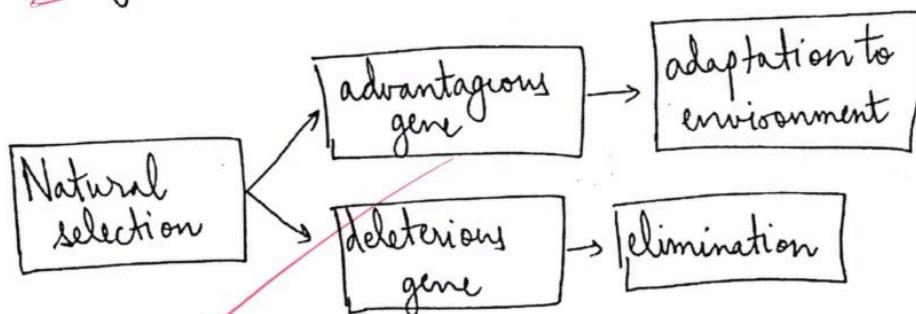

Natural selection is the process by which individual adapt to environment through selective reproduction

According to Darwin, it is natural selection which ~~helps~~ leads to elimination or enhancement of species based on certain traits.

If these traits are advantageous like HbA/HbS in Mediterranean region, then species adapt to environment. However if they are deleterious, then natural selection ~~against~~ act against it & eliminate it.

Today's world

- A change in single base pair of amino acid makes HbA to HbS. This results in individual having resistance to malarial ~~action~~ infection.
- If a Rh(-ve) mother have Rh(+ve) offspring, then natural selection acts on it, it is eliminated by a process called ~~erythroblastosis~~ ~~erythroblastic~~ erythroblastosis fetalis.

- ~~Various~~ study A study published in ~~Lancet~~ Lancet, tibetans have developed unique genes (EGLN1 & EPAS1 genes) which prevents complications like blood cottage due to low oxygen levels.

~~Hence~~, the effect of natural selection can also be seen in today's world.

~~It~~ operates on individuals with other factors like gene mutation, hybridisation, genetic drift etc to result in evolution.
