(d) Convergent evolution and parallel evolution

Evolution in genetic sense is change in gene frequencies.

When there is morphological similarity between two species, then there can be phylogenetic relationship between both. This can ~~be~~ explained through convergent and parallel evolution.

Convergent evolution

1) When two different species evolve independently a common function, then it is called convergent evolution.

2) It is analogous in nature - ~~fact~~ origin ~~of~~ of species is different but function is similar.

L2A™

convergent evolution

Parallel evolution

1) When two species of same ancestor evolve into a similar function, then it is called parallel evolution.

2) It is homologous in nature - origin and function both are same.

Parallel evolution

Hence, convergent and divergent evolution provide a new insight and dimension in understanding the process of evolution.
