5.c) Immunological Method of Man-Family study

Immunological method
refers to the study of substrates & processes involved in human immunity.
immunological processes like Antibodies, B cells, T cells, etc.

The normal functionally study & the study of deviation helps us to study the understand human variation.

Methods used in Immunogenetics

1) Electrophoresis - It is used to separate the different segments of DNA in order to understand their sequencing.

2) Blotting techniques - It consists of various types like

i) Southern Blotting - used to segregate DNA & study

- ii) Northern blotting - study RNA sequences
- iii) Western blotting - study of proteins

3) Antibody - Antigen reactions

It forms the basis of most immunological methods.
For instance,

- i) ELISA test - Enzyme linked Immunosorbent assay - helps detect the antigen (e.g.) HIV infection
- ii) Rapid Antigen test - faster detection of antigen
- iii) PCR test - Polymerase chain reaction test to identify the viral / pathogen sequence from bio sample.

Therefore, these methods are crucial in health diagnosis & management especially during era of pandemics.
