1.b) Twin study method and Co-twin method

Twin study method refers to specialised study under Man-Family group of studies. It refers to studying the twins in certain environment to understand the proportional role of nature & nurture.

While co-twin study is part of Twin studies specifically wherein monozygotic twins are reared apart & then studied to understand the role of nature & nurture.

Important Case studies under Twin studies:

1) US Army Obesity study

- 4000 twin pairs were studied to determine the proportion of role of nature & nurture. It found that genetics played important role than environment in weight gain.

2) Eric Turkheimer's IQ heritability test

found that genetics played important role in IQ when sufficient environment for growth was given (Affluent families) while environment played role in deprived families (labor class).

Case studies for Co-twin Method

1) Minnesota test

2) Chicago test

They found that there was difference in acquisition of skill between 2 identical twins reared apart but the one who was left behind always catches up.

Here, these studies 170 added immensely to central debate of Anthropology.
