1.e) Fertility and Fecundity

Fertility refers to the average number of child born to a couple (especially women) in her reproductive age.

Fecundity refers to the biological capacity of the women to give birth to the children. It depends upon the hormones, ovaries, eggs and the uterus (her organs)

Relation between them

① Fertility depends upon the fecundity.

② Fertility takes the socio-cultural factor like → Age of Marriage
→ Live-in-relation
→ Use of Contraceptives
Family planning & other aspects.

③ Fecundity depends upon the nutrition, genes and the hormonal aspect in the women physiology.

④ A women can be fecund but not fertile, but not the vice-versa.

⑤ The urban Complexities decide the fertility; More resources more child growth and vice-versa.

⑥ For greater care and nurturing of the grand children women can forgone her fertility but it doesn't mean, she is not fecund (Herbert Spencer biology theory)

Hence, both fertility and fecundity are the crucial stages in the women reproductive life and the population dynamics
