Q.2) (a) Discuss physiological and social theories of ageing.

(20 marks)

Ageing is the process of growing older, our chronological age is increasing and we are tending towards becoming old.

With the process of growing old, there are physiological or biological theories and social theories connected to ageing.

### Physiological theories

These theories focus on our biological health and ability of our genes to handle the old age problems.

(1) Genetic blueprint → It is called Hayflick limit ⇒ the number of

time, a cell will divide is pre-programmed. It is because of telomere attrition and there is genetic clock embedded in the nucleus of the cell.

② Free Radical :→ The reactive  $O_2$  species reacts with lipids → forming lipofuscin ⇒ Impacting the functioning of the organs and its functions.

③ Brain as a pace maker :→ With the age, Catecholamine is not efficiently released by Brain → Causing the imbalance in hormones.

④ Error theory :→ The DNA repair mechanism is becoming ineffective.

⑤ Disposible soma theory :->

We humans come with definite amount of energy. We can either use it for maintenance of our self-growth or for Reproduction,

But, in keeping the energy only for our maintenance, there is risk that we can be killed by Animals or natural Calastrophe; so balance it with reproduction.

### Social theory of Ageing

① Disengagement theory (Cumming & Henry)

↳ The old age individual recede from social gathering.

(Eg) Male will not take the decision of family & Female will not go in child-b<sup>ir</sup> or family functions
