(c) Explain the Heath and Carter method in human somatotypes

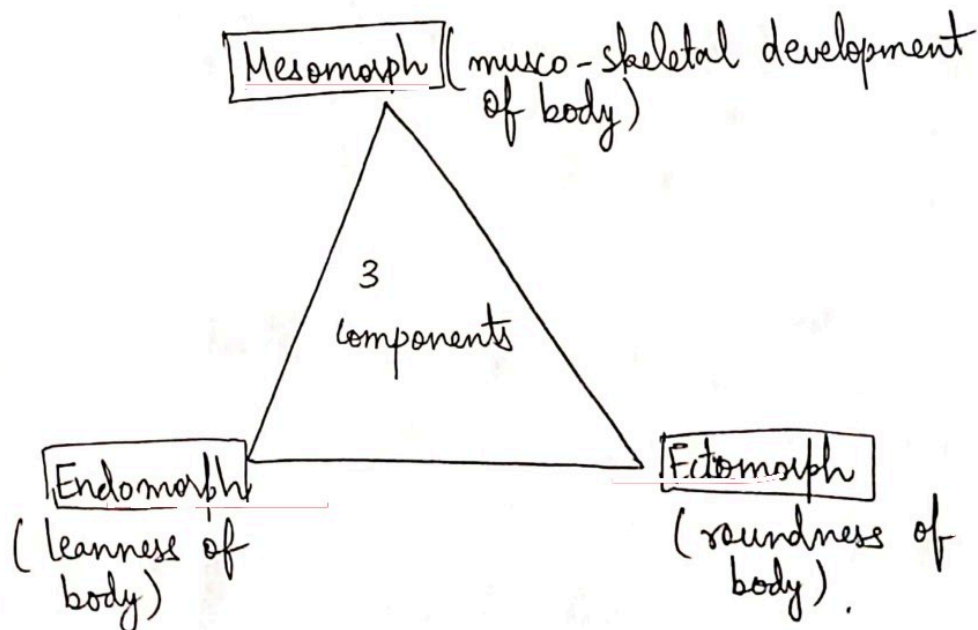

Somatotypes are the analysis of & study of human body. According to Heath & Carter (1973) it is the present human morphological configuration.

Background

Book : Somatotyping: Development and Applications

- Sheldon method (1940) had many flaws, drawing upon that Heath & Carter devised a new method in 1973.

Classification

L2A™

Do not

this margin

Criteria

- Heath & Carter used 15 parameters like height, weight etc. and devised a score for each component.

Endomorph - 1-15

Mesomorph - 1-12

Ectomorph - 0.5-9

Difference with Sheldon method

- > While Sheldon measured it ~~only~~ ^{by} static method, Heath & Carter measured the population on current basis.

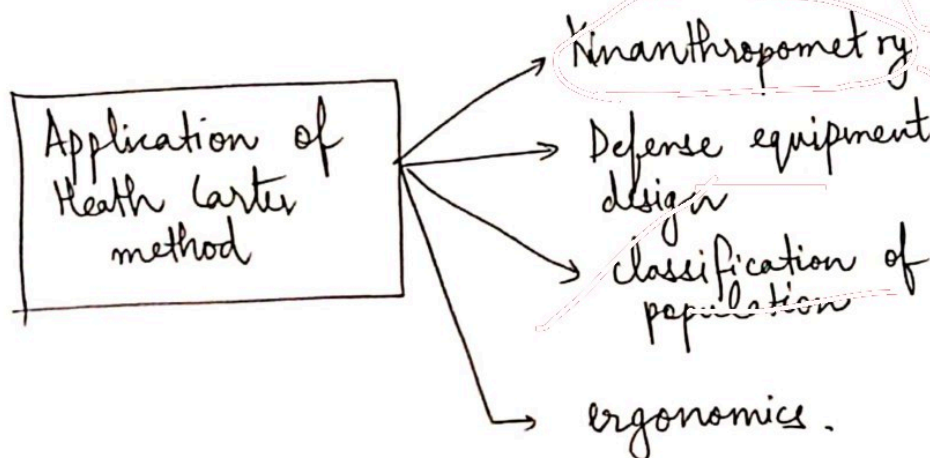

Evaluation

- 1) It is a objective criteria which holistically covers many aspects
- 2) Females are also included.
- 3) Workable in both laboratory & field.

- 4) It is easy, accurate & efficient
- 5) Can be used to measure spatial as well as temporal variations.

Hence, Heath & Carter method is most scientifically accurate method to measure human somatotypes.

You can also mention its relation to selection of sport persons
